Abstract

We propose deterministic timed automata (DTA) as a model-independent language for specifying performance and dependability measures over continuous-time stochastic processes. Technically, these measures are defined as limit frequencies of locations (control states) of a DTA that observes computations of a given stochastic process. Then, we study the properties of DTA measures over semi-Markov processes in greater detail. We show that DTA measures over semi-Markov processes are well-defined with probability one, and there are only finitely many values that can be assumed by these measures with positive probability. We also give an algorithm which approximates these values and the associated probabilities up to an arbitrarily small given precision. Thus, we obtain a general and effective framework for analysing DTA measures over semi-Markov processes.

1 Conclusions

We have shown that DTA measures over semi-Markov processes are well-defined for almost all runs and assume only finitely many values with positive probability. We also indicated how to approximate DTA measures and the associated probabilities up to an arbitrarily small given precision.

Our approximation algorithm is quite naive and there is a lot of space for further improvement. An interesting open question is whether one can design more efficient algorithms with low complexity in the size of SMP (the size of DTA specifications should stay relatively small in most applications, and hence the (inevitable) exponential blowup in the size of DTA is actually not so problematic).

Another interesting question is whether the results presented in this paper can be extended to more general stochastic models such as generalized semi-Markov processes.

Acknowledgement

The authors thank Petr Slovák for his many useful comments.
